VHDL-based fault injection techniques. Simulator commands technique is based on the use of the simulator commands to modify the value of the model signals and variables without altering the VHDL code. VHDL code modification techniques change the model, adding saboteurs,, or using mutants of the model components,,.

The signals where faults can be injected are those which connect components in structural models. In [6] we can see a classification of saboteurs: serial and parallel. Serial saboteurs are VHDL components that are inserted between the output port (s) of a component and the input port (s) of its connected component.

This paper describes a new methodology to inject transient and permanent faults in digital systems. For this purpose, the simulation based fault injector VERIFY (VHDL-based Evaluation of Reliability by Injecting Faults efficiently) has been developed, which allows fault injection at several abstraction levels of a digital system.

Abstract This paper presents a VHDL-based simulated fault injection (SFI) methodology for quantum circuits. The main objective is to attain a high error modeling capability at a technology independent level. For this purpose, gate level simulation models for quantum circuits have been developed using VHDL.

The simulation-based fault injection technique uses the VHDL model as the target system, and it usually includes two implementation methods: modifying the VHDL model and altering the value of signals and variables defined in the prototype. The modification of VHDL model mainly uses the saboteur or mutation method.

SEU Fault-Injection in VHDL-Based Processors: A Case Study

If you're looking for fault injection in a real circuit you'll want to be simulating the netlist. Rtl (particularly vhdl) will use enumerated types for state machines that will be encoded by the synthesizer. What application are you looking at? Fault injection is not something I've ever done, but I'm in commercial space.
